1.	ENCRYPTION/DECRYPTION FOR SUBSTITUTION TECHNIQUES
Ex. No: 1a	CAESAR CIPHER (SHIFT CIPHER)

AIM

To implement a program for encrypting a plain text and decrypting a cipher text using Caesar Cipher (shift cipher) substitution technique.

ALGORITHM DESCRIPTION

It is a type of substitution cipher in which each letter in the plaintext is replaced by a letter some fixed number of positions down the alphabet. For example, with a left shift of 3, D would be replaced by A, E would become B, and so on. The method is named after Julius Caesar, who used it in his private correspondence. The transformation can be represented by aligning two alphabets; the cipher alphabet is the plain alphabet rotated left or right by some number of positions. The encryption can also be represented using modular arithmetic by first transforming the letters into numbers, according to the scheme, A = 0, B = 1,..., Z = 25.

Encryption of a letter x by a shift n can be described mathematically as,

$$E_n(x) = (x+n) \bmod 26$$

Decryption is performed similarly,

$$D_n(x) = (x-n) \bmod 26$$

Procedure for Encryption:

1. Read 'Key' value to shift.
2. Read the **Plaintext** to encrypt.
3. Initialize **Cipher Text** with empty string.
4. Convert each character into Upper text.
5. Read each character 'current' in a PlainText.
 - a. Find ASCII value of current character and add key with that.
 - b. Find, $\text{Sum} \leftarrow \text{ASCII}(\text{current}) + \text{key}$
 - c. Subtract 65 from sum, $\text{Sum} \leftarrow \text{Sum} - 65$
 - d. Do modulo division with 26, $\text{Sum} \leftarrow \text{Sum} \bmod 26$
 - e. Compute encrypted char by adding 65, $\text{Encrypted} \leftarrow 65 + \text{Sum}$
 - f. Add **Encrypted** character to **CipherText**.
6. Repeat step 5 until all characters encrypted.

PANIMALAR ENGINEERING COLLEGE

Department of CSE

Reg no: 211420104033

Procedure for Decryption:

1. Read 'Key' value to shift.
2. Read the **CipherText** to Decrypt.
3. Initialize **PlainText** with empty string.
4. Convert each character into Upper text.
5. Read each character 'current' in a **CipherText**.
 - a. Find ASCII value of current character and subtract key with that.
 - b. Find, $\text{Sum} \leftarrow \text{ASCII}(\text{current}) \text{ MOD } 65$.
 - c. Subtract **key** from sum, $\text{Diff} \leftarrow \text{Sum} - \text{key}$
 - d. If **Diff** is less than zero, $\text{Diff} \leftarrow 26 - \text{Diff}$
 - e. Compute **Decrypted** character by adding 65, $\text{Decrypted} \leftarrow 65 + \text{Diff}$
 - f. Add **Decrypted** character to **PlainText**.
6. Repeat step 5 until all characters Decrypted.

1.	ENCRYPTION/DECRYPTION FOR SUBSTITUTION TECHNIQUES
Ex. No: 1b	PLAYFAIR CIPHER

AIM

To implement a program to encrypt a plain text and decrypt a cipher text using play fair Cipher substitution technique.

ALGORITHM DESCRIPTION

The Playfair cipher uses a 5 by 5 table containing a key word or phrase. To generate the key table, first fill the spaces in the table with the letters of the keyword, then fill the remaining spaces with the rest of the letters of the alphabet in order (usually omitting "Q" to reduce the alphabet to fit; other versions put both "I" and "J" in the same space). The key can be written in the top rows of the table, from left to right, or in some other pattern, such as a spiral beginning in the upper-left-hand corner and ending in the centre.

The keyword together with the conventions for filling in the 5 by 5 table constitutes the cipher key. To encrypt a message, one would break the message into digrams (groups of 2 letters) such that, for example, "HelloWorld" becomes "HE LL OW OR LD", and map them out on the key table. Then apply the following 4 rules, to each pair of letters in the plaintext:

1. If both letters are the same (or only one letter is left), add an "X" after the first letter. Encrypt the new pair and continue. Some variants of Playfair use "Q" instead of "X", but any letter, itself uncommon as a repeated pair, will do.
2. If the letters appear on the same row of your table, replace them with the letters to their immediate right respectively (wrapping around to the left side of the row if a letter in the original pair was on the right side of the row).
3. If the letters appear on the same column of your table, replace them with the letters immediately below respectively (wrapping around to the top side of the column if a letter in the original pair was on the bottom side of the column).
4. If the letters are not on the same row or column, replace them with the letters on the same row respectively but at the other pair of corners of the rectangle defined by the original pair. The order is important – the first letter of the encrypted pair is the one that lies on the same row as the first letter of the plaintext pair.

To decrypt, use the INVERSE (opposite) of the last 3 rules, and the 1st as-is (dropping any extra "X"s, or "Q"s that do not make sense in the final message when finished).

PANIMALAR ENGINEERING COLLEGE

Department of CSE

Reg no: 211420104033

Procedure for Encryption:

1. Read the key.
2. Read the Plaintext.
3. Initialize the PlayFair table array as 5x5 two dimensional array.
4. Add each character of the key in the array without duplicates.
5. Add alphabets from A,B..Z in the remaining array positions without duplicates.
6. Read First two characters from the Plaintext and find their locations (R1, C1), (R2, C2) in array.
 - a. If $R1=R2$, then the characters at the position (R1, $(C1+1\%5)$) and (R2, $(C2+1\%5)$) are the equivalent Cipher Text.
 - b. Otherwise, the characters at location (R1, C2) and (R2, C1) are the equivalent Cipher Text.

Repeat step 6 until all characters converted into Cipher Text.

Procedure for Decryption:

1. Read the key.
2. Read the Cipher Text.
3. Initialize the PlayFair table array as 5x5 two dimensional array.
4. Add each character of the key in the array without duplicates.
5. Add alphabets from A, B...Z in the remaining array positions without duplicates.
6. Read First two characters from the Cipher Text and find their locations (R1, C1), (R2, C2) in array.
 - a. If $R1=R2$, then the characters at the position (R1, $(C1-1\%5)$) and (R2, $(C2-1\%5)$) are the equivalent Plaintext.
 - b. Otherwise, the characters at location (R1, C2) and (R2, C1) are the equivalent Cipher Text.

Repeat step 6 until all characters converted into Plaintext.

1.	ENCRYPTION/DECRYPTION FOR SUBSTITUTION TECHNIQUES
Ex. No: 1c	HILL CIPHER

AIM

To implement a program to encrypt and decrypt using the Hill cipher substitution technique.

ALGORITHM DESCRIPTION

The Hill cipher is a substitution cipher invented by Lester S. Hill in 1929. Each letter is represented by a number modulo 26. To encrypt a message, each block of n letters is multiplied by an invertible $n \times n$ matrix, again modulus 26.

To decrypt the message, each block is multiplied by the inverse of the matrix used for encryption. The matrix used for encryption is the cipher key, and it should be chosen randomly from the set of invertible $n \times n$ matrices (modulo 26).

The cipher can, be adapted to an alphabet with any number of letters. All arithmetic just needs to be done modulo the number of letters instead of modulo 26.

Procedure for Encryption:

1. Read the key size 'N'.
2. Read the Key matrix.
3. Read the Plaintext.
4. Split Plaintext into group of N characters.
5. Convert each group into column matrix. With the ASCII (character) Mod 26.
6. Multiply each group column matrix by Key matrix. Do modulo division by 26 with the result.
7. Add 65 with each value in the resultant Matrix.
8. Add the ASCII character equivalent of the resultant matrix elements to the Cipher Text.

Repeat step 5 to 8 until all characters converted into Cipher Text.

Procedure for Decryption:

1. Read the key size 'N'.
2. Read the Key matrix.
3. Read the CipherText.
4. Split CipherText into group of N characters.
5. Convert each group into column matrix. With the ASCII (character) Mod 26.
6. Multiply each group column matrix by inverse of Key matrix. Do modulo division by 26 with the result.
7. Add 65 with each value in the resultant Matrix.
8. Add the ASCII character equivalent of the resultant matrix elements to the Plaintext.

1.	ENCRYPTION/DECRYPTION FOR SUBSTITUTION TECHNIQUES
Ex. No: 1d	VIGENERE CIPHER

AIM

To implement a program for encryption and decryption using vigenere cipher substitution technique.

ALGORITHM DESCRIPTION

The Vigenere cipher is a method of encrypting alphabetic text by using a series of different Caesar ciphers based on the letters of a keyword. It is a simple form of polyalphabetic substitution. To encrypt, a table of alphabets can be used, termed a Vigenere square, or Vigenere table. It consists of the alphabet written out 26 times in different rows, each alphabet shifted cyclically to the left compared to the previous alphabet, corresponding to the 26 possible Caesar ciphers. At different points in the encryption process, the cipher uses a different alphabet from one of the rows used. The alphabet at each point depends on a repeating keyword.

Procedure for Encryption:

1. Read the Key.
2. Read the PlainText.
3. Initialize keyindex to 0 and CipherText to empty.
4. Read each character (P) in the Plaintext, and key character(K) at position keyindex.
5. Compute $PV \leftarrow \text{ASCII}(P) \text{ MOD } 26$ and $KV \leftarrow \text{ASCII}(K) \text{ MOD } 26$
6. Add PV and KV and do modulo division, $SUM \leftarrow (PV + KV) \text{ MOD } 26$.
7. Add 65 with the Sum and Generate ASCII character corresponding to the resultant Sum. The resultant character is the Cipher equivalent of current character. Add it to the CipherText.
8. Increment keyindex. If keyindex reaches LENGTH(Key), initialize eyindex-0)

Procedure for decryption:

1. Read the Key.
2. Read the CipherText.
3. Initialize keyindex to 0 and CipherText to empty.
4. Read each character (C) in the Plaintext, and key character(K) at position keyindex.
5. Compute $CV \leftarrow \text{ASCII}(C) \text{ MOD } 26$ and $KV \leftarrow \text{ASCII}(K) \text{ MOD } 26$
6. Compute $Sum \leftarrow (26 - KV) + CV \text{ MOD } 26$.
7. Add 65 with the Sum and Generate ASCII character corresponding to the resultant Sum. The resultant character is the PlainText equivalent of current character. Add it to the PlainText.
8. Increment keyindex. If keyindex reaches LENGTH(Key), initialize keyindex-0)

Repeat steps from 4 to 8 until all characters encrypted.

2.	ENCRYPTION/DECRYPTION FOR TRANSPOSITION TECHNIQUES
Ex. No: 2a	RAILFENCE CIPHER

AIM

To implement a program for encryption and decryption using rail fence transposition technique.

ALGORITHM DESCRIPTION

In the rail fence cipher, the plaintext is written downwards and diagonally on successive "rails" of an imaginary fence, then moving up when we reach the bottom rail. When we reach the top rail, the message is written downwards again until the whole plaintext is written out. The message is then read off in rows.

Procedure for Encryption:

1. Read the Key lines N.
2. Read the PlainText.
3. For each line l in N
4. Calculate the offset corresponding to the line.
5. Read the characters from the PlainText in the index $l, l+offset*1, l+offset*2$.
6. Add the characters to the Ciphertext.
7. Increment line by 1. Repeat steps 4 to 6 for all lines.

Procedure for Decryption:

1. Read the Key lines N.
2. Read the CipherText.
3. For each line l in N
4. Calculate the offset corresponding to the line.
5. Read the characters from the CipherText in the index $l, l+offset*1, l+offset*2$.
6. Add the characters to the PlainText.
7. Increment line by 1. Repeat steps 4 to 6 for all lines.

2.	ENCRYPTION/DECRYPTION FOR TRANSPOSITION TECHNIQUES
Ex. No: 2b	ROW AND COLUMN TRANSPOSITION

AIM

To implement a program for encryption and decryption using row and column transposition technique.

ALGORITHM DESCRIPTION

A Columnar transposition also known as row-column transpose is a very simple cipher to perform by hand. The name of the cipher comes after the operations on a matrix that are performed during both, encryption and decryption. The number of columns of the matrix is determined by the secret key. The secret key is usually a word (or just a sequence of letters). It has to be converted into a sequence of numbers. The numbers are defined by an alphabetical order of the letters in the keyword. The letter which is first in the alphabet will be the number 1; the second letter in the alphabetical order will be 2, and so on. If there are multiple identical letters in the keyword, each next occurrence of the same letter should be converted into a number that is equal to the number for the previous occurrence increased by one.

Procedure for Encryption:

In a transposition cipher, the order of the alphabets is re-arranged to obtain the cipher-text.

1. The message is written out in rows of a fixed length, and then read out again column by column, and the columns are chosen in some scrambled order.
2. Width of the rows and the permutation of the columns are usually defined by a keyword.
3. For example, the word HACK is of length 4 (so the rows are of length 4), and the permutation is defined by the alphabetical order of the letters in the keyword. In this case, the order would be "3 1 2 4".
4. Any spare spaces are filled with nulls or left blank or placed by a character (Example: _).
5. Finally, the message is read off in columns, in the order specified by the keyword.

Procedure for Decryption:

1. To decipher it, the recipient has to work out the column lengths by dividing the message length by the key length.
2. Then, write the message out in columns again, then re-order the columns by reforming the key word.

Ex. No: 3	NETWORK SECURITY ALGORITHMS
	DATA ENCRYPTION STANDARD (DES) ALGORITHM

AIM

To develop a program to implement Data Encryption Standard for Encryption and Decryption for practical applications.

ALGORITHM DESCRIPTION

The Data Encryption Standard (DES) is a symmetric-key block cipher published by the National Institute of Standards and Technology (NIST). DES is an implementation of a Feistel Cipher. It uses 16 round Feistel structure. The block size is 64-bit. Though, key length is 64-bit, DES has an effective key length of 56 bits, since 8 of the 64 bits of the key are not used by the encryption algorithm (function as check bits only). General Structure of DES is depicted in the following illustration

Since DES is based on the Feistel Cipher, all that is required to specify DES is –

- Round function
- Key schedule
- Any additional processing – Initial and final permutation

PANIMALAR ENGINEERING COLLEGE

Department of CSE

Reg no: 211420104033

ALGORITHM

1. The 64-bit plain text block is handed over to an **Initial Permutation (IP)** function.
2. The Initial Permutation (IP) produces two halves of the permuted block; say **Left Plain Text (LPT)** and **Right Plain Text (RPT)**.
3. Now each of LPT and RPT go through 16 rounds of encryption process.
4. In the end. LPT and RPT are joined and a Final Permutation (FP) is performed on the combined block.
5. The result of this process produces 64-bit cipher text.

Ex. No: 4	NETWORK SECURITY ALGORITHMS
	ADVANCED ENCRYPTION STANDARD (AES) ALGORITHM

AIM

To develop a program to implement Advanced Encryption Standard for encryption and decryption for practical applications.

ALGORITHM DESCRIPTION

Advanced Encryption Standard (AES) is a symmetric block cipher chosen by the U.S government to protect classified information. AES is implemented in software and hardware throughout the world to encrypt sensitive data. The National Institute of Standards and Technology (NIST) started development of AES in 1997 when it announced the need for an alternative to the Data Encryption Standard (DES), which was starting to become vulnerable to brute-force attacks.

The three variants of AES are based on different key sizes (128, 192, and 256 bits). In this article, we will focus on the 128-bit version of the AES key schedule, which provides sufficient background to understand the 192 and 256 bit variants as well. At the end, we'll include a note the other variants, and how they differ from the 128-bit version.

Encryption with AES

The encryption phase of AES can be broken into three phases: the initial round, the main rounds, and the final round. All of the phases use the same sub-operations in different combinations as follows:

- Initial Round

AddRoundKey

- Main Rounds

SubBytes

ShiftRows

MixColumns

AddRoundKey

- Final Round

SubBytes

ShiftRows

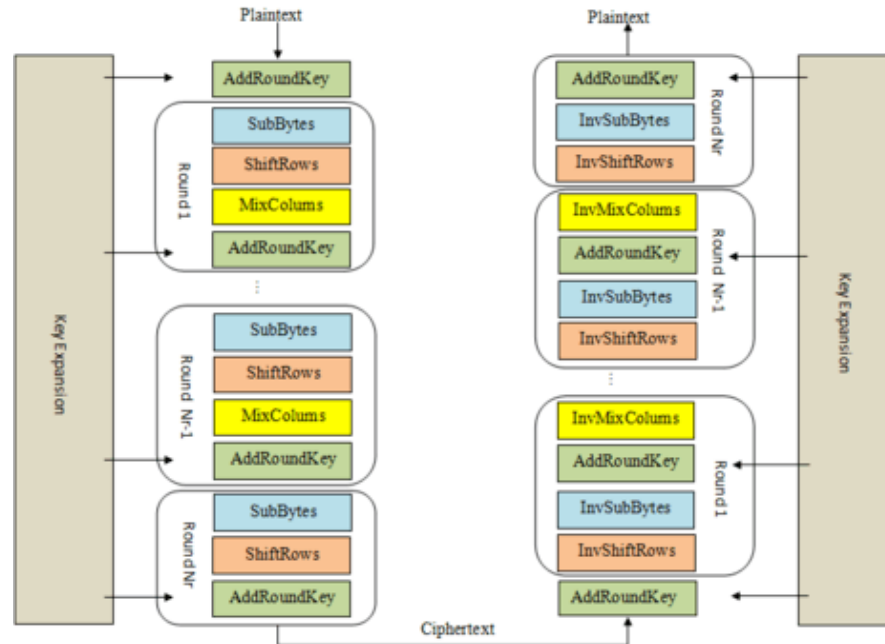

AddRoundKey

PANIMALAR ENGINEERING COLLEGE

Department of CSE

Reg no: 211420104033

The main rounds of AES are repeated a set number of times for each variant of AES. AES-128 uses 9 iterations of the main round, AES-192 uses 11, and AES-256 uses 13.

Overall structure of encryption and decryption in Advanced Encryption Standard

ALGORITHM

(Encryption of a 128 bit block)

1. Derive the set of round keys from the cipher key
2. Initialize the state array with the block data (plaintext)
3. Add the initial round key to the starting state array
4. Perform nine rounds of state manipulation.
5. Perform the tenth and final round of state manipulation
6. Copy the final state array out as the encrypted data (ciphertext)

The reason that the rounds have been listed as “nine followed by a final tenth round” is because the tenth round involves a slightly different manipulation from the others.

Ex. No: 5	NETWORK SECURITY ALGORITHMS
	RIVEST SHAMIR ADLEMAN (RSA) ALGORITHM

AIM

Develop a program to implement RSA algorithm for encryption and decryption using HTML and JavaScript

This cryptosystem is one the initial system. It remains most employed cryptosystem even today. The system was invented by three scholars **Ron Rivest**, **Adi Shamir**, and **Len Adleman** and hence, it is termed as RSA cryptosystem. The two aspects of the RSA cryptosystem, first the generation of key pair and second the encryption-decryption algorithms.

ALGORITHM DESCRIPTION

Generation of RSA Key Pair

Each person or a party who desires to participate in communication using encryption needs to generate a pair of keys, namely public key and private key. The process followed in the generation of keys is described below –

- **Generate the RSA modulus (n)**
 - Select two large primes, p and q.
 - Calculate $n=p*q$. For strong unbreakable encryption, let n be a large number, typically a minimum of 512 bits.
- **Find Derived Number (e)**
 - Number e must be greater than 1 and less than $(p - 1)(q - 1)$.
 - There must be no common factor for e and $(p - 1)(q - 1)$ except for 1. In other words two numbers e and $(p - 1)(q - 1)$ are coprime.
- **Form the public key**
 - The pair of numbers (n, e) form the RSA public key and is made public.
 - Interestingly, though n is part of the public key, difficulty in factorizing a large prime number ensures that attacker cannot find in finite time the two primes (p & q) used to obtain n. This is strength of RSA.
- **Generate the private key**
 - Private Key d is calculated from p, q, and e. For given n and e, there is unique number d.

PANIMALAR ENGINEERING COLLEGE

Department of CSE

Reg no: 211420104033

- Number d is the inverse of e modulo $(p - 1)(q - 1)$. This means that d is the number less than $(p - 1)(q - 1)$ such that when multiplied by e , it is equal to 1 modulo $(p - 1)(q - 1)$.
- This relationship is written mathematically as follows $ed = 1 \bmod (p - 1)(q - 1)$

The Extended Euclidean Algorithm takes p , q , and e as input and gives d as output

ENCRYPTION AND DECRYPTION

Once the key pair has been generated, the process of encryption and decryption are relatively straightforward and computationally easy.

Interestingly, RSA does not directly operate on strings of bits as in case of symmetric key encryption. It operates on numbers modulo n . Hence, it is necessary to represent the plaintext as a series of numbers less than n .

RSA Encryption

- Suppose the sender wish to send some text message to someone whose public key is (n, e) .
- The sender then represents the plaintext as a series of numbers less than n .
- To encrypt the first plaintext P , which is a number modulo n . The encryption process is simple mathematical step as $C = P^e \bmod n$
- In other words, the ciphertext C is equal to the plaintext P multiplied by itself e times and then reduced modulo n . This means that C is also a number less than n .
- Returning to our Key Generation example with plaintext $P = 10$, we get ciphertext C

$$C = 10^5 \bmod 91$$

RSA Decryption

- The decryption process for RSA is also very straightforward. Suppose that the receiver of public-key pair (n, e) has received a ciphertext C .
- Receiver raises C to the power of his private key d . The result modulo n will be the plaintext P .

$$\text{Plaintext} = C^d \bmod n$$

- Returning again to our numerical example, the ciphertext $C = 82$ would get decrypted to number 10 using private key 29 – Plaintext = $82^{29} \bmod 91 = 10$

Ex. No: 6	NETWORK SECURITY ALGORITHMS
	DIFFIE-HELLMAN KEY EXCHANGE ALGORITHM

AIM

Develop a program to implement Diffie Hellman Key Exchange Algorithm for encryption and Decryption.

ALGORITHM DESCRIPTION

Diffie–Hellman key exchange (D–H) is a specific method of securely exchanging cryptographic keys over a public channel and was one of the first public-key protocols. The Diffie–Hellman key exchange method allows two parties that have no prior knowledge of each other to jointly establish a shared secret key over an insecure channel. This key can then be used to encrypt subsequent communications using a symmetric key cipher.

Algorithm

1. Global Public Elements:

Let q be a prime number and α where $\alpha < q$ and α is a primitive root of q .

2. User A Key Generation:

Select private X_A where $X_A < q$

Calculate public Y_A where $Y_A = \alpha^{X_A} \bmod q$

3. User B Key Generation:

Select private X_B where $X_B < q$

Calculate public Y_B where $Y_B = \alpha^{X_B} \bmod q$

4. Calculation of Secret Key by User A

$$K = (Y_B)^{X_A} \bmod q$$

5. Calculation of Secret Key by User B:

$$K = (Y_A)^{X_B} \bmod q$$

Ex. No: 7	MESSAGE DIGEST
	SECURE HASH FUNCTION (SHA-1) ALGORITHM

AIM

To calculate the message digests of a text using Secure Hash Algorithm (SHA-1)

The **Secure Hash Algorithm** is a family of cryptographic hash functions published by the National Institute of Standards and Technology (NIST) as a U.S. Federal Information Processing Standard (FIPS), including:

- **SHA-0:** A retronym applied to the original version of the 160-bit hash function published in 1993 under the name "SHA". It was withdrawn shortly after publication due to an undisclosed "significant flaw" and replaced by the slightly revised version SHA-1.
- **SHA-1:** A 160-bit hash function which resembles the earlier MD5 algorithm. This was designed by the National Security Agency (NSA) to be part of the Digital Signature Algorithm. Cryptographic weaknesses were discovered in SHA-1, and the standard was no longer approved for most cryptographic uses after 2010.
- **SHA-2:** A family of two similar hash functions, with different block sizes, known as *SHA-256* and *SHA-512*. They differ in the word size; SHA-256 uses 32-bit words where SHA-512 uses 64-bit words. There are also truncated versions of each standard, known as *SHA-224*, *SHA-384*, *SHA-512/224* and *SHA-512/256*. These were also designed by the NSA.
- **SHA-3:** A hash function formerly called *Keccak*, chosen in 2012 after a public competition among non-NSA designers. It supports the same hash lengths as SHA-2, and its internal structure differs significantly from the rest of the SHA family.

ALGORITHM DESCRIPTION

Secured Hash Algorithm-1 (SHA-1):

Step 1: Append Padding Bits....

Message is "padded" with a 1 and as many 0's as necessary to bring the message length to 64 bits fewer than an even multiple of 512.

Step 2: Append Length....

64 bits are appended to the end of the padded message. These bits hold the binary format of 64 bits indicating the length of the original message.

Step 3: Prepare Processing Functions....

SHA1 requires 80 processing functions defined as:

PANIMALAR ENGINEERING COLLEGE

Department of CSE

Reg no: 211420104033

$$f(t;B,C,D) = (B \text{ AND } C) \text{ OR } ((\text{NOT } B) \text{ AND } D) \quad (0 \leq t \leq 19)$$

$$f(t;B,C,D) = B \text{ XOR } C \text{ XOR } D \quad (20 \leq t \leq 39)$$

$$f(t;B,C,D) = (B \text{ AND } C) \text{ OR } (B \text{ AND } D) \text{ OR } (C \text{ AND } D) \quad (40 \leq t \leq 59)$$

$$f(t;B,C,D) = B \text{ XOR } C \text{ XOR } D \quad (60 \leq t \leq 79)$$

Step 4: Prepare Processing Constants....

SHA1 requires 80 processing constant words defined as:

$$K(t) = 0x5A827999 \quad (0 \leq t \leq 19)$$

$$K(t) = 0x6ED9EBA1 \quad (20 \leq t \leq 39)$$

$$K(t) = 0x8F1BBCDC \quad (40 \leq t \leq 59)$$

$$K(t) = 0xCA62C1D6 \quad (60 \leq t \leq 79)$$

Step 5: Initialize Buffers....

SHA1 requires 160 bits or 5 buffers of words (32 bits):

$$H0 = 0x67452301$$

$$H1 = 0xEFCDAB89$$

$$H2 = 0x98BADCFE$$

$$H3 = 0x10325476$$

$$H4 = 0xC3D2E1F0$$

Step 6: Processing Message in 512-bit blocks (L blocks in total message)....

This is the main task of SHA1 algorithm which loops through the padded and appended message in 512-bit blocks.

Input and predefined functions: $M[1, 2, \dots, L]$: Blocks of the padded and appended message

$f(0;B,C,D), f(1;B,C,D), \dots, f(79;B,C,D)$: 80 Processing Functions $K(0), K(1), \dots, K(79)$: 80 Processing Constant Words

$H0, H1, H2, H3, H4, H5$: 5 Word buffers with initial values

$H0, H1, H2, H3, H4, H5$: 5 Word buffers with initial values

Step 6: Pseudo Code....

For loop on $k = 1$ to L

$$(W(0), W(1), \dots, W(15)) = M[k] \text{ /* Divide } M[k] \text{ into 16 words */}$$

For $t = 16$ to 79 do:

$$W(t) = (W(t-3) \text{ XOR } W(t-8) \text{ XOR } W(t-14) \text{ XOR } W(t-16)) \lll 1$$

$$A = H0, B = H1, C = H2, D = H3, E = H4$$

PANIMALAR ENGINEERING COLLEGE

Department of CSE

Reg no: 211420104033

For t = 0 to 79 do:

TEMP = A<<<5 + f(t;B,C,D) + E + W(t) + K(t) E = D, D = C,

C = B<<<30, B = A, A = TEMP

End of for loop

H0 = H0 + A, H1 = H1 + B, H2 = H2 + C, H3 = H3 + D, H4 = H4 + E

End of for loop

RESULT

Thus the program for implementing Secure Hash Function (SHA-1) algorithm is done using java and output is verified successfully.

PANIMALAR ENGINEERING COLLEGE

Department of CSE

Reg no: 211420104033

Ex. No: 8	SIGNATURE SCHEME
	DIGITAL SIGNATURE STANDARD

AIM

To write a program to implement the digital signature scheme in java

ALGORITHM DESCRIPTION

The use and verification of digital signatures is a standard engine that is included in the security provider architecture. Like the other engines, the classes that implement this engine have both a public interface and an SPI for implementers of the engine.

In the JDK, the most common use of digital signatures is to create signed classes. Users have the option of granting additional privileges to these signed classes using the mechanics of the access controller. In addition, a security manager and a class loader can use this information to change the policy of the security manager.

DESIGN

The following global public key components are chosen in key generation

p is a random l -bit prime, $512 \leq l \leq 1024$, $l = 64t$, where $t = 8, \dots, 16$

q is a random 160-bit prime dividing $p-1$

$r = h^{(p-1)/q} \bmod p$, where h is a random primitive element of Z_p , such that $r > 1$

User Key Components

x is a private key which is random integer $0 < x < q$

$y = r^x \bmod p$

Therefore the key = (p, q, r, x, y)

After computing the key, User A publish the key (p, q, r, y) in public directory.

SIGNATURE

Signature of a 160-bit plaintext w to be sent

Choose a random number k , where $0 < k < q$ such that $\gcd(k, q) = 1$

Compute $a = (r^k \bmod p) \bmod q$

Compute $b = k^{-1} (w + xa) \bmod q$, (or) $bk = (w + xa) \bmod q$ where $kk^{-1} \equiv 1 \pmod{q}$

Signature: $\text{sig}(w, k) = (a, b)$

PANIMALAR ENGINEERING COLLEGE

Department of CSE

Reg no: 211420104033

VERIFICATION

Verification of Signature (a, b)

Compute $z = b^{-1} \bmod q$

Compute $u_1 = wz \bmod q$, $u_2 = az \bmod q$

Verification: $\text{Ver}_k(w, a, b) = \text{true}$

PROGRAM → **SIGNATURE VERIFICATION**

```
import java.io.IOException;

public class ObjectSigningExample {
    public static void main(String[] args) {
        try {
            // Generate a 1024-bit Digital Signature Algorithm (DSA) key pair
            KeyPairGenerator keyPairGenerator = KeyPairGenerator.getInstance("DSA");
            keyPairGenerator.initialize(1024);
            KeyPair keyPair = keyPairGenerator.genKeyPair();
            PrivateKey privateKey = keyPair.getPrivate();
            PublicKey publicKey = keyPair.getPublic();
            // We can sign Serializable objects only
            String unsignedObject = new String("A Test Object");
            Signature signature = Signature.getInstance(privateKey.getAlgorithm());
            SignedObject signedObject = new SignedObject(unsignedObject, privateKey, signature);
            // Verify the signed object
```

PANIMALAR ENGINEERING COLLEGE

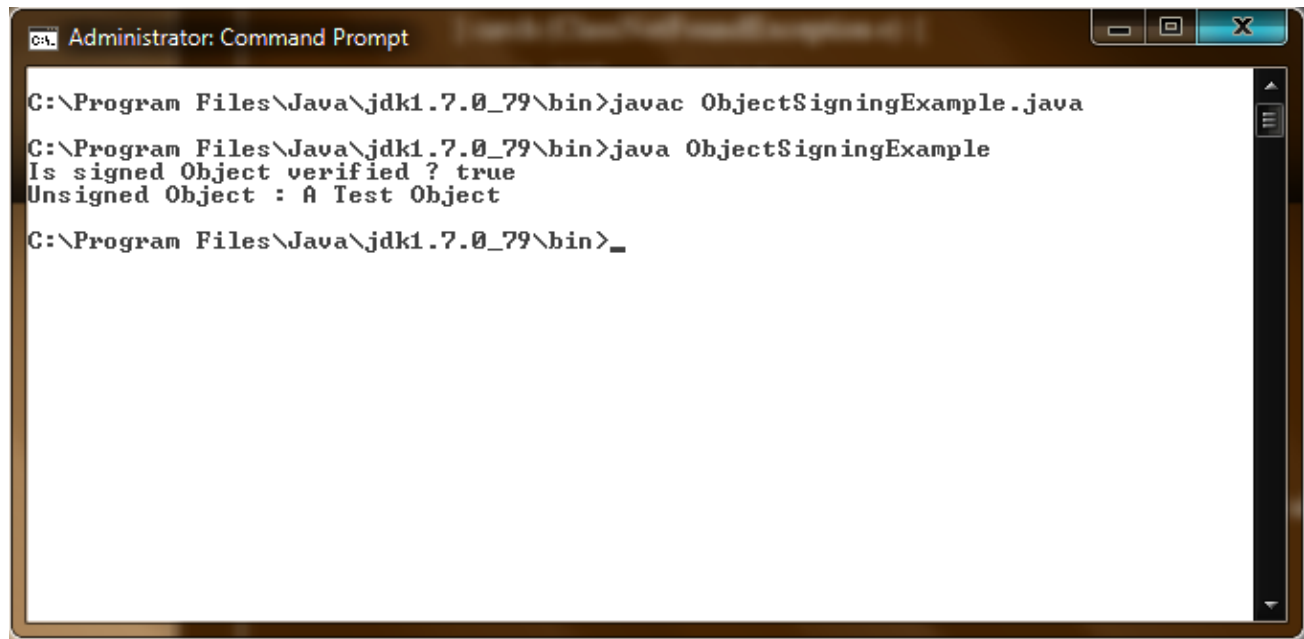

Department of CSE

Reg no: 211420104033

```
Signature sig = Signature.getInstance(publicKey.getAlgorithm());
boolean verified = signedObject.verify(publicKey, sig);
System.out.println("Is signed Object verified ? " + verified);

    // Retrieve the object
unsignedObject = (String) signedObject.getObject();
System.out.println("Unsigned Object : " + unsignedObject);
} catch (SignatureException e) {
} catch (InvalidKeyException e) {
} catch (NoSuchAlgorithmException e) {
} catch (ClassNotFoundException e) {
} catch (IOException e) {
}}}
```

OUTPUT

A screenshot of a Windows Command Prompt window titled "Administrator: Command Prompt". The window shows the following commands and output:

```
C:\Program Files\Java\jdk1.7.0_79\bin>javac ObjectSigningExample.java
C:\Program Files\Java\jdk1.7.0_79\bin>java ObjectSigningExample
Is signed Object verified ? true
Unsigned Object : A Test Object
C:\Program Files\Java\jdk1.7.0_79\bin>_
```

RESULT:

Thus the program for implementing Digital Signature Scheme (DSS) using Digital Signature Standard (DSA) algorithm is done using java and output is verified successfully.

PANIMALAR ENGINEERING COLLEGE

Department of CSE

Reg no: 211420104033

Ex. No: 9	INTRUSION DETECTION SYSTEM (IDS)
	SNORT

AIM

To demonstrate Intrusion Detection System (IDS) using Snort Tool.

Snort Description:

Snort is an open source network intrusion detection system (NIDS) has the ability to perform real-time traffic analysis and packet logging on internet protocol (IP) networks. Snort performs protocol analysis, content searching and matching.

Snort can be configured in three main modes: sniffer, packet logger, and network intrusion detection.

SNIFER MODE

In sniffer mode, the program will read network packets and display them on the console.

snort -v Show the TCP/IP packets header on the screen

snort -vd Show the TCP/IP ICMP header with application data in transmit

PACKET LOGGER MODE

In packet logger mode, the program will log packets to the disk.

`snort -dev -l c:\snort\log` [create this directory in the C drive] and snort will automatically know to go into packet logger mode, it collects every packet it sees and places it in log directory

snort -dev -l c:\snort\log -h ipaddress/24	This rule informs snort that you want to print out the data link and TCP/IP headers as well as application data into the log directory
---	--

```
snort -l c:\snort\log -b
```

This is binary mode logs everything into a single file

NETWORK INTRUSION DETECTION SYSTEM MODE

In intrusion detection mode, the program will monitor network traffic and analyze it against a rule set defined by the user. The program will then perform a specific action based on what has been identified.

snort -d c:\snort\log -h ipaddress/24 -c snort.conf	This is a configuration file applies rule to each packet to decide it an action based upon the rule type in the file
---	--

`snort -d -h ipaddress/24 -l c:\snort\log -c` This will configure snort to run in its most

PANIMALAR ENGINEERING COLLEGE

Department of CSE

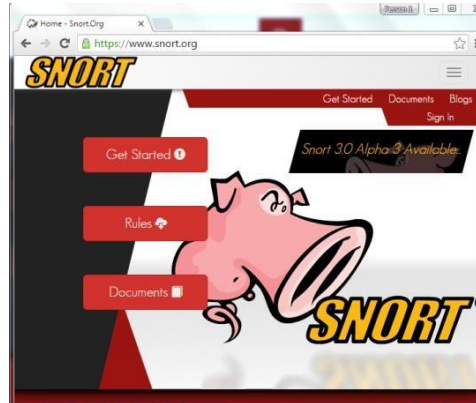

Reg no: 211420104033

snort.conf

basic NIDS (Network Intrusion Detection System) form, logging packets that trigger rules specified in the snort.conf

PROCEDURE

1. Download SNORT from snort.org

2. Get Started [Download the latest version] from the windows tab at this point the latest version is **snort_2_9_8_2_installer.exe**
3. Rules [Download the latest version] based on version downloaded **snortrules-snapshot-2982.tat.gz**
4. Download WinPcap from WinPcap.org [version 4.1.3]
5. Place the installer, rules, winPcap in snort folder
6. Download zenmap from nmap.org **nmap-7.12-setup.exe**

a. How to Configure snort?

Move to c drive → snort → etc folder → snort.conf [open with wordpad]

Step 1: Change the path

setup the network addresses you are protecting

ipvar HOME_NET any

change this to your current system ip address using

ipvar HOME_NET 192.168.1.2/24 [you could get the ip of the system using ipconfig command]

PANIMALAR ENGINEERING COLLEGE

Department of CSE

Reg no: 211420104033

Fig. IPConfig Command

#setup the external network address

ipvar EXTERNAL_NET \$HOME_NET

Rule Path

var RULE_PATH ../rules

var PREPROC_RULE_PATH ../preproc_rules

Change the path as

var RULE_PATH C:\Snort\rules

var SO_RULE_PATH ../so_rules

var PREPROC_RULE_PATH C:\Snort\preproc_rules

If you are using reputation preprocessor set these

var WHITE_LIST_PATH C:\Snort\rules

var BLACK_LIST_PATH C:\Snort\rules

Step 2: Configure the decoder

In the last line config logdir: add config logdir: C:\Snort\log [remove # symbol]

Step 3: Set path for Dynamic Preprocessor and Dynamic Engine

path to dynamic preprocessor libraries

dynamicpreprocessor directory C:\Snort\lib\snort_dynamicpreprocessor

path to base preprocessor engine

dynamicengine C:\Snort\lib\snort_dynamicengine\sf_engine.dll

PANIMALAR ENGINEERING COLLEGE

Department of CSE

Reg no: 211420104033

```
# path to dynamic rules libraries [Assign # symbol to dynamic detection directory]
```

```
# dynamicdetection directory /usr/local/lib/snort_dynamicrules
```

Step 4: Configure Preprocessors

Assign # symbol in following lines

```
# Inline packet normalization. For more information, see README.normalize
```

```
# Does nothing in IDS mode
```

```
# preprocessor normalize_ip4
```

```
# preprocessor normalize_tcp: block, rsv, pad, urp, req_urg,
```

```
# req_pay, req_urp, ips, ecn stream
```

```
# preprocessor normalize_icmp4
```

```
# preprocessor normalize_ip6
```

```
# preprocessor normalize_icmp6
```

In the last line add

```
# Reputation preprocessor. For more information see README.reputation
```

```
preprocessor reputation: \
```

```
    memcap 500, \
```

```
    priority whitelist, \
```

```
    nested_ip inner, \
```

```
    whitelist $WHITE_LIST_PATH/white.list, \
```

```
    blacklist $BLACK_LIST_PATH/black.list
```

Step 5: Customizing Rule Sheet

Change backward slash to forward slash in the following codes

```
# site specific rules
```

```
include $RULE_PATH\local.rules
```

```
include $RULE_PATH\app-detect.rules
```

```
include $RULE_PATH\attack-responses.rules
```

```
.
```

```
.
```

```
.
```

PANIMALAR ENGINEERING COLLEGE

Department of CSE

Reg no: 211420104033

```
include $RULE_PATH\x11.rules
```

Step 6: Customizing Preprocessor

Change backward slash to forward slash in the following codes [also remove # symbol in the below three lines]

```
# decoder and preprocessor event rules
```

```
include $PREPROC_RULE_PATH\preprocessor.rules
```

```
include $PREPROC_RULE_PATH\decoder.rules
```

```
include $PREPROC_RULE_PATH\sensitive-data.rules
```

Check whether you have the line threshold.conf in the last line of snort.conf

b. How to use Snort to detect Ping?

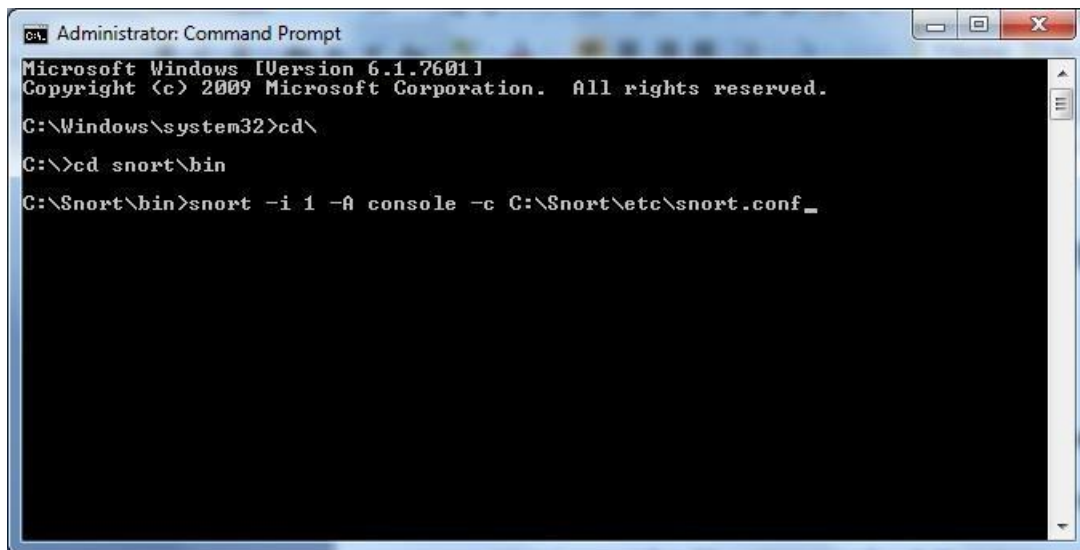

Step 1: In snort folder in c drive go to rules folder

open icmp.rules file using wordpad then type

```
alert icmp any any -> any any (msg:"PING PING PING"; sid:1000000001;)
```

Step 2 : Open Command Prompt Run as Administrator

In command prompt type the following command

```
Administrator: Command Prompt
Microsoft Windows [Version 6.1.7601]
Copyright (c) 2009 Microsoft Corporation. All rights reserved.

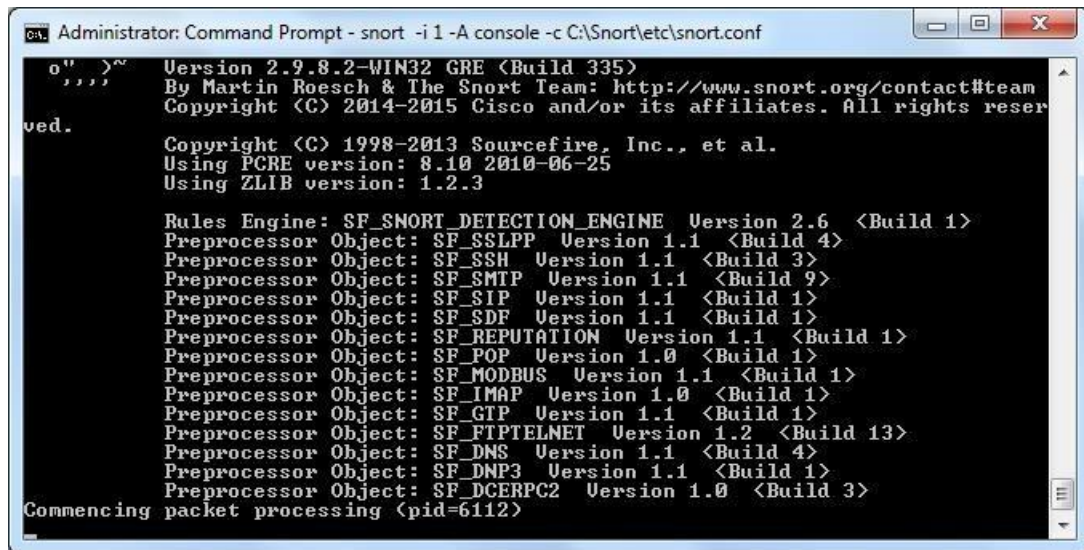

C:\Windows\system32>cd\
C:\>cd snort\bin
C:\Snort\bin>snort -i 1 -A console -c C:\Snort\etc\snort.conf_
```

wait until you get the line **commencing packet processing**

PANIMALAR ENGINEERING COLLEGE

Department of CSE

Reg no: 211420104033

```
Administrator: Command Prompt - snort -i 1 -A console -c C:\Snort\etc\snort.conf

C.

How to use Snort to log portscan?

Step 1: Move to log folder in snort create a blank text file name it as say sample.txt

PANIMALAR ENGINEERING COLLEGE

Department of CSE

Reg no: 211420104033

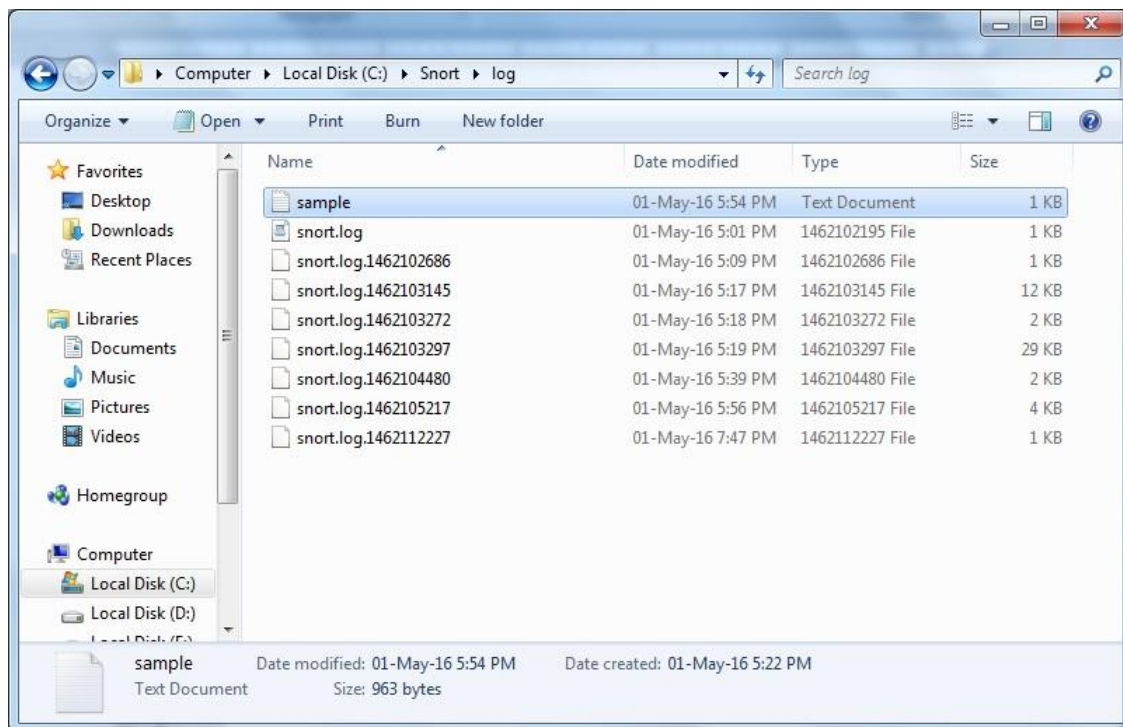

Fig. Sample.txt in log folder

Step 2: Open snort.conf using [ctrl+F] find stream5_global

check whether it as the same line

Target-Based stateful inspection/stream reassembly. For more information, see README.stream5

preprocessor stream5_global: track_tcp yes, \

track_udp yes, \

track_icmp no, \

max_tcp 262144, \

max_udp 131072, \

max_active_responses 4, \

min_response_seconds 2

Next find for portscan

Portscan detection. For more information, see README.sfportscan

preprocessor stream5_global: track_udp yes track_tcp yes

preprocessor sfportscan: proto { all } scan_type { all } sense_level { medium } logfile { **sample.txt** }

PANIMALAR ENGINEERING COLLEGE

Department of CSE

Reg no: 211420104033

//the file name should be same as created in log folder

Step 3: Open zenmap type the google ip obtained from ping command in target

Fig. Zenmap Home Page

Step 4: Before commencing scan open the command prompt [run as administrator] type the following command

snort -i 1 -A console -c C:\Snort\etc\snort.conf

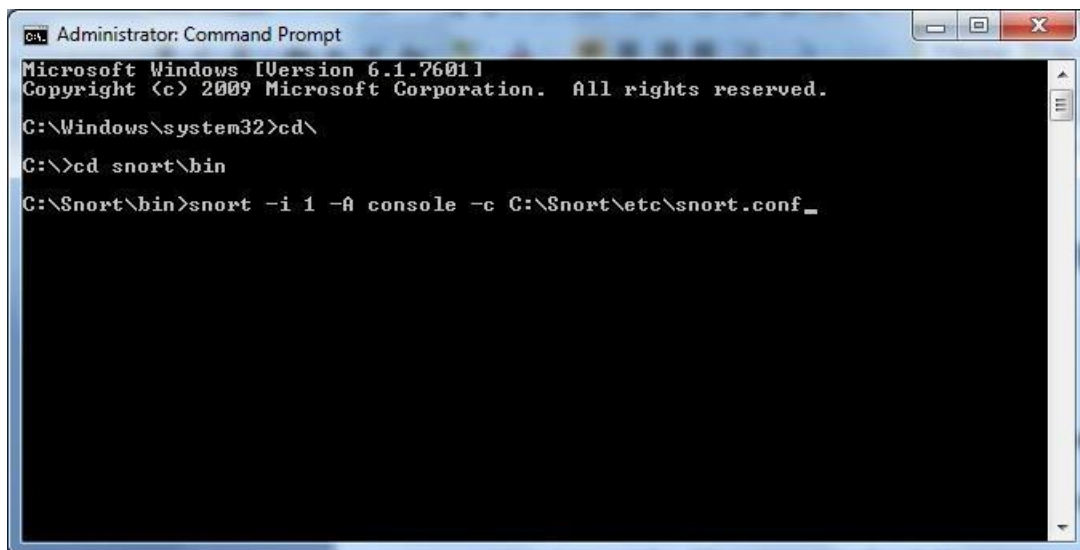

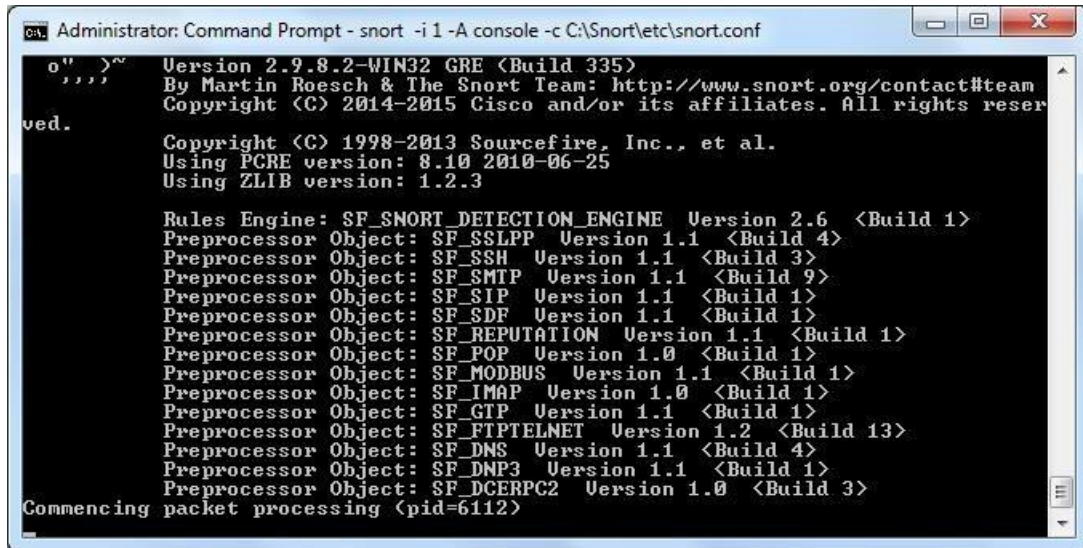

Fig. Commencing Snort

PANIMALAR ENGINEERING COLLEGE

Department of CSE

Ex. No: 10	AUTOMATED ATTACK AND PENETRATION TOOLS
	EXPLORING N-STALKER

AIM

To explore N-Stalker, a vulnerability Assessment Tool

DESCRIPTION

N-Stalker is a web server security-auditing tool that scans for more than 30,000 vulnerabilities. N-Stalker was created in April 2000 by Information Security Technology specialists, aiming at providing solutions to protect corporations and individuals against digital threats that affect information systems. The first product to be released was N-Stealth HTTP Security Scanner Suite, a complete set of tools to assess Web servers' security, including the capabilities of identifying vulnerabilities and providing a possible solution to mitigate the risks from critical mission business infrastructure, either on the Internet or in a corporate environment.

By permanently making use of attack signature updates, the software has aggregated the most extensive and updated database available on the market, with more than 39,000 vulnerabilities and exploits for Web environments, recursively utilized by the scanning tool.

Steps:

You need to download and install N-Stalker from www.nstalker.com

1. Start N-Stalker from a windows computer by choosing Start→Programs→N-Stalker→N-Stalker Free Edition.
2. In the web application URL field enter a host address or a range of addresses to scan.
3. Click start scan
4. After the scan is complete, the N-Stalker Report Manager prompts you to select a format for the resulting report. Choose Generate HTML.
5. Review the HTML report for vulnerabilities.

Armed with this report, your next step should be to set priorities on which services should be patched and hardened.

PANIMALAR ENGINEERING COLLEGE

Department of CSE

Reg no: 211420104033

Fig. N-Stalker to scan for Vulnerabilities

RESULT

Thus the demonstration of Vulnerability Assessment Tool is explored using N-Stalker Assessment Tool and performance is analyzed.

Reg no: 211420104033

Ex. No: 11a	DEFEATING MALWARE
	BUILDING TROJANS

AIM

To build Simple Trojans Programs and check their performance.

DESCRIPTION

Trojans are programs that seem to do something you want but actually perform another, malicious, act. Before a Trojan program can act, it must trick the user into downloading it or performing some type of action. The Trojan may be configured to do many things, such as log keystrokes, add the user's system to a botnet, or even give the attacker full access to the victim's computer. A user may think that a file looks harmless and is safe to run but, once executed, it delivers its malicious payload. Unlike a virus or worm, Trojans cannot spread themselves. They rely on the uninformed user

TASK:

Trojans and malware pose a real danger. This challenge highlights one of the ways that a hacker may distribute a Trojan. By default, older Windows systems automatically start a CD when it is inserted in the CD tray. You use this technique to distribute simulated malicious code. You need a blank CD and a CD burner for this exercise.

1. Create a text file named autorun.ini. Inside this text file, add the following contents:
[autorun]
Open paint.exe
Icon=paint.exe
2. Place the autorun.ini file and a copy of paint.exe into a folder to be burned to a CD.
3. After you have burned the CD, reinsert it in the CD-ROM drive and observe the results. The CD should autostart and automatically starts the Paint program.
4. Think about the results. Although this exercise was benign, you could have easily used a Trojan program wrapped with a legitimate piece of software. Just leaving the CD lying around or giving it an attractive title, such as "pending 2006 bonuses," may lead someone to pick it up and view its contents. Anyone running the CD would then become infected. Even with AutoRun turned off, the user would only have to double-click the CD-ROM icon and the program would still run.

PANIMALAR ENGINEERING COLLEGE

Department of CSE

Reg no: 211420104033

RESULT

Thus the Simple Trojan Programs is done and their performance is checked.

Ex. No: 11b	DEFEATING MALWARE
	ROOT KIT HUNTER

AIM

To install root kits and study about variety of options.

RootKit Description:

Rootkit is a stealth type of malicious software designed to hide the existence of certain process from normal methods of detection and enables continued privileged access to a computer

PROCEDURE

- Download Rootkit Tool from GMER website. www.gmer.net
- This displays the Processes, Modules, Services, Files, Registry, RootKit/Malwares, Autostart, CMD of local host.
- Select Processes menu and kill any unwanted process if any. Modules menu displays the various system files like .sys, .dll
- Services menu displays the complete services running with Autostart, Enable, Disable, System, and Boot.
- Files menu displays full files on Hard-Disk volumes.
- Registry displays Hkey_Current_user and Hkey_Local_Machine. Rootkits/Malawares scans the local drives selected.
- Autostart displays the registry base Autostart applications.

CMD allows the user to interact with command line utilities or Registry

Ex. No: 12	ADDITIONAL EXPERIMENTS
	IMPLEMENT MESSAGE DIGEST (MD5) ALGORITHM

AIM

Develop a program to implement Message Digest Algorithm.

ALGORITHM DESCRIPTION

The MD5 **message-digest algorithm** is a widely used **cryptographic hash function** producing a 128-bit (16-byte) **hash value**, typically expressed in text format as a 32-digit hexadecimal number. MD5 has been utilized in a wide variety of cryptographic applications and is also commonly used to verify data integrity.

MD5 Algorithm:

We begin by supposing that we have a b -bit message as input, and that we wish to find its message digest. Here b is an arbitrary nonnegative integer; b may be zero, it need not be a multiple of eight, and it may be arbitrarily large. We imagine the bits of the message written down as follows:

$m_0 m_1 \dots m_{b-1}$

The following five steps are performed to compute the message digest of the message.

Step 1. Append Padding Bits:

The message is "padded" (extended) so that its length (in bits) is congruent to 448, modulo 512. That is, the message is extended so that it is just 64 bits shy of being a multiple of 512 bits long. Padding is always performed, even if the length of the message is already congruent to 448, modulo 512. Padding is performed as follows: a single "1" bit is appended to the message, and then "0" bits are appended so that the length in bits of the padded message becomes congruent to 448, modulo 512. In all, at least one bit and at most 512 bits are appended.

Step 2. Append Length:

A 64-bit representation of b (the length of the message before the padding bits were added) is appended to the result of the previous step. In the unlikely event that b is greater than 2^{64} , then only the low-order 64 bits of b are used. (These bits are appended as two 32-bit words and appended low-order word first in accordance with the previous conventions.) At this point the resulting message (after padding with bits and with b) has a length that is an exact multiple of 512

PANIMALAR ENGINEERING COLLEGE

Department of CSE

Reg no: 211420104033

bits. Equivalently, this message has a length that is an exact multiple of 16 (32-bit) words. Let $M[0 \dots N-1]$ denote the words of the resulting message, where N is a multiple of 16.

Step 3. Initialize MD Buffer:

A four-word buffer (A,B,C,D) is used to compute the message digest. Here each of A, B, C, D is a 32-bit register. These registers are initialized to the following values in hexadecimal, low-order bytes first):

word A: 01 23 45 67

word B: 89 ab cd ef

word C: fe dc ba 98

word D: 76 54 32 10

Step 4. Process Message in 16-Word Blocks:

We first define four auxiliary functions that each take as input three 32-bit words and produce as output one 32-bit word.

$$F(X,Y,Z) = XY \vee \text{not}(X) Z$$

$$G(X,Y,Z) = XZ \vee Y \text{ not}(Z)$$

$$H(X,Y,Z) = X \text{ xor } Y \text{ xor } Z$$

$I(X,Y,Z) = Y \text{ xor } (X \vee \text{not}(Z))$ In each bit position F acts as a conditional: if X then Y else Z . The function F could have been defined using $+$ instead of \vee since XY and $\text{not}(X)Z$ will never have 1's in the same bit position.) It is interesting to note that if the bits of X , Y , and Z are independent and unbiased, the each bit of $F(X,Y,Z)$ will be independent and unbiased.

The functions G , H , and I are similar to the function F , in that they act in "bitwise parallel" to produce their output from the bits of X , Y , and Z , in such a manner that if the corresponding bits of X , Y , and Z are independent and unbiased, then each bit of $G(X,Y,Z)$, $H(X,Y,Z)$, and $I(X,Y,Z)$ will be independent and unbiased. Note that the function H is the bit-wise "xor" or "parity" function of its inputs.

This step uses a 64-element table $T[1 \dots 64]$ constructed from the sine function. Let $T[i]$ denote the i -th element of the table, which is equal to the integer part of $4294967296 \text{ times } \text{abs}(\sin(i))$, where i is in radians. The elements of the table are given in the appendix.

Department of CSE

Reg no: 211420104033

Example:

```
/* Process each 16-word block. */
```

```
For i = 0 to N/16-1 do
```

```
/* Copy block i into X. */
```

```
For j = 0 to 15 do
```

```
Set X[j] to M[i*16+j].
```

```
end /* of loop on j */
```

```
/* Save A as AA, B as BB, C as CC, and D as DD. */
```

```
AA = A
```

```
BB = B
```

```
CC = C
```

```
DD = D
```

```
/* Round 1. */
```

```
/* Let [abcd k s i] denote the operation
```

```
a = b + ((a + F(b,c,d) + X[k] + T[i]) <<< s). */
```

```
/* Do the following 16 operations. */
```

```
[ABCD 0 7 1] [DABC 1 12 2] [CDAB 2 17 3] [BCDA 3 22 4]
```

```

Ex. No: 13	ADDITIONAL EXPERIMENTS
	DEMONSTRATE HOW TO PROVIDE SECURE DATA STORAGE, SECURE DATA TRANSMISSION AND FOR CREATING DIGITAL SIGNATURE (GnuPG)

AIM

To write a program to demonstrate how to provide secure data storage, secure data transmission and how to create digital signatures.

GnuPG Description:

GnuPG is a complete and free implementation of the OpenPGP standard as defined by RFC4880. GnuPG allows to encrypt and sign our data and communication, features a versatile key management system as well as access modules for all kinds of public key directories. GnuPG, also known as GPG, is a command line tool with features for easy integration with other applications.

PROCEDURE

i) Generate the Key

1. Open GPA (GNU Privacy Assistant) from Start → GPA.
2. Open Key Manager, by selecting Window → Keyring Manager.
3. Select New Key, by selecting Keys → New key.
4. Generate key by Selecting Algorithm, Key Size and specify Name, Email also check Expires if you want to specify key expiry date and Click Ok.
5. Enter '**passphrase**' a secret key to protect your keys. (ex: **cnslab**)
6. Re-enter '**passphrase**' to confirm.
7. If the '**passphrase**' is not strength, a dialog will be shown. Click "Take this one anyway" if you do not want to change phrase key. Otherwise if you want to change the "passphrase", click "Enter new passphrase".
8. Repeat steps 1 to 8 to create keys for another user. (Ex: receiver@gmail.com)

ii) Encrypt and Sign Text

1. Open GPA (GNU Privacy Assistant) from Start → GPA.
2. Type the message to encrypt and sign in Clipboard.
3. Click Encrypt, in the tool bar,
4. Select the public key of the receiver to Encrypt and for sign select the sender private key. and click Ok.

PANIMALAR ENGINEERING COLLEGE

Department of CSE

Reg no: 211420104033

5. Enter the 'passphrase' keyword of the sender.
6. The Encrypted and signed message will be shown,
7. Copy and save the encrypted message in text file.(message.txt)

iii) Decrypt and verify Message received.

1. Open GPA (GNU Privacy Assistant) from Start→GPA.
2. Under Clipboard paste the content of the message.txt.
3. Click **Encrypt** menu in tool bar,
4. Enter the receivers "passphrase" to decrypt the message.
5. The Decrypted message will be shown in, GNU Privacy assistant – Clipboard.

iv) Encrypt and Sign a File

1. Create a folder SEND and copy the file to be encrypted in it(**Ex:**Input.txt)
2. Open GPA (GNU Privacy Assistant) from Start→GPA.
3. Open the file manager by selecting, menu "Files" in toolbar,
4. Open the file "Input.txt" by clicking "Open" menu in Tool bar,
5. The select the file will be loaded in file Manager.
6. Select the file in File manager window and click Encrypt.
7. Select the Public Key of the receiver and select the sign key.
8. Enter the "passphrase" of the sender to Sign.
9. The new encrypted file(Input.txt.gpg) will be generated in the same folder contains the extension .gpg.
10. The file Input.txt.gpg is the Encrypted and digitally signed.

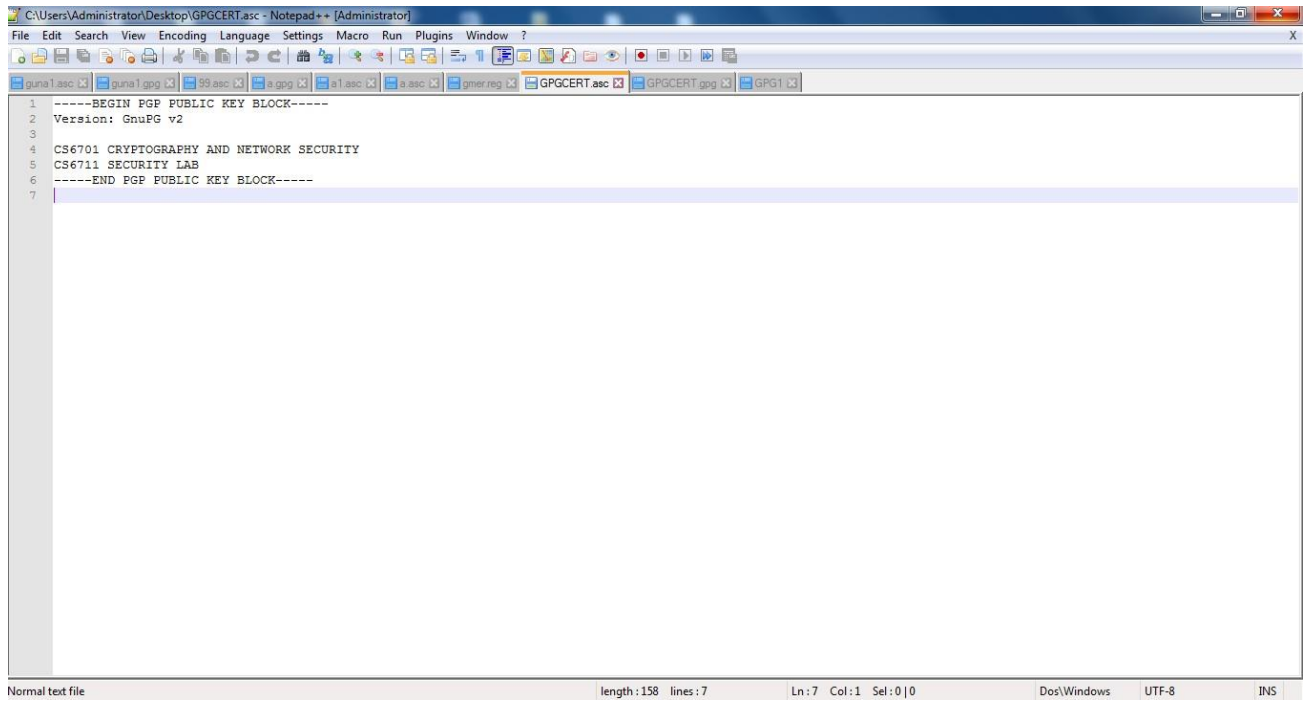

v) Decrypt and Verify Encrypted Signed File

1. Copy the Encrypted file Input.txt.gpg in new folder "Receive".
2. Open File manager, and select the file Input.txt.gpg in folder "Receive".
3. Select the File, Input.txt.gpg in the file manager, and click Decrypt.
4. Enter the "passphrase" of the receiver, and click Ok.
5. The sender Signature will be verified, and the status is shown as valid.
6. The Decrypted file "**Input.txt**" will be in the folder "Receive".

Ex. No: 14	ADDITIONAL EXPERIMENTS
	SETUP A HONEY POT AND MONITOR THE HONEY POT ON NETWORK

AIM

To setup a honey pot and to monitor the honey pot on network.

HoneyPot Description:

Honey Pot is a device placed on Computer Network specifically designed to capture malicious network traffic.

KF Sensor is the tool to setup as honeypot when KF Sensor is running it places a siren icon in the windows system tray in the bottom right of the screen. If there are no alerts then green icon is displayed.

PROCEDURE

- Download KF Sensor Evaluation Set File from KF Sensor Website. Install with License Agreement and appropriate directory path. Reboot the Computer now.
- The KF Sensor automatically starts during windows boot Click Next to setup wizard. Select all port classes to include and Click Next.
- Send the email and Send from email enter the ID and Click Next.
- Select the options such as Denial of Service [DOS], Port Activity, Proxy Emulsion, Network Port Analyzer, Click Next.
- Select Install as System service and Click Next.
- Click finish.
